

mini Bunion™

A Rapid Return to Real Life

Bunions can be painful and unsightly. One of the main reasons bunion-sufferers avoid surgery is concerns about how long they will be off their feet unable to take care of themselves or their responsibilities.

This is why CrossRoads Extremity Systems developed the miniBunion™ procedure; a cutting edge minimally-invasive bunion surgery technique to repair bunions. Unlike traditional procedures, the miniBunion™ technique requires a tiny incision, only 1 to 2 centimeters in length, much smaller than a standard technique and requires much less trauma to the soft-tissues surrounding the toes. This minimally-invasive technique spares the blood supply to the bones and allows a smaller scar and faster rehabilitation.

The miniBunion™ scar is not only small, it is in a location that is difficult for anyone to see. Unlike most bunion procedures where the incision is on the top of the foot, the miniBunion™ incision is on the inner side of the foot. This location results in a scar that is basically invisible during day-to-day activities.
